horizontal circulation

Horticultural fans

If you want to improve the growing environment in greenhouse cultivation and reduce temperature and humidity variations to a minimum, the Enfan horticultural fan is the right solution. The various models allow you to create the best air circulation under all circumstances. For this, the fans are installed according to the parallel or serial method.

Type FG and ZN

The FG and ZN fans are distinguishable in terms of return on investement and noise level. The unique shaped fan blades, with toothed edges (FE2owlet), give the fans an efficient result and a low sound pressure level. The throw is wider than other fans and this creates a soft motion of air. The Enfan is available with 2 types of fans: FG and ZN. The higher capacity of type ZN (6000 m³/h*) in comparison to type FG (3600 m³/h) makes the difference. This will make the Enfan a perfect fan for use in greenhouses. * without grids

Rotation control

The rotation is controlled by transformers that are available in a simple small 1-phase version and large 3-phase versions that can be controlled by a computer. The rotation speed is regulated through five fixed steps.

Suspension support

When the fan is suspended on the short brackets, it often hangs under the rafter. Using the long brackets, the fan can be suspended to a maximum of 45 cm under the rafter, which allows the air stream to encounter less resistance. The carefully designed suspension support with oblique lip is made in such a way that the screen is tilted upwards by the bracket and can therefore fit flush to the rafter.

Parallel system

If the fan is used in combination with an LVM installation, the parallel system is a good choice, regardless the size of the greenhouse.

Serial system

With greenhouses becoming larger, the serial system with several fans in a row is being used more and more. In this way, all the air in the greenhouse is kept moving. A serial system can also be combined well with LVM.

Serial system 3×3

A disadvantage in large greenhouses can be that there is often an uncontrolled air movement. This "natural draught" in the greenhouse can change every day and often causes the throw of the fan to be deflected so that it does not reach the next fan. This is not beneficial to the serial system. To solve this problem, the so-called 3×3 system has been developed. By allowing 3 rows placed next to each other to blow in the same direction, the air stream becomes stronger and is no longer deflected. In this way, the air will always be moved from one end of the greenhouse to the other.
